

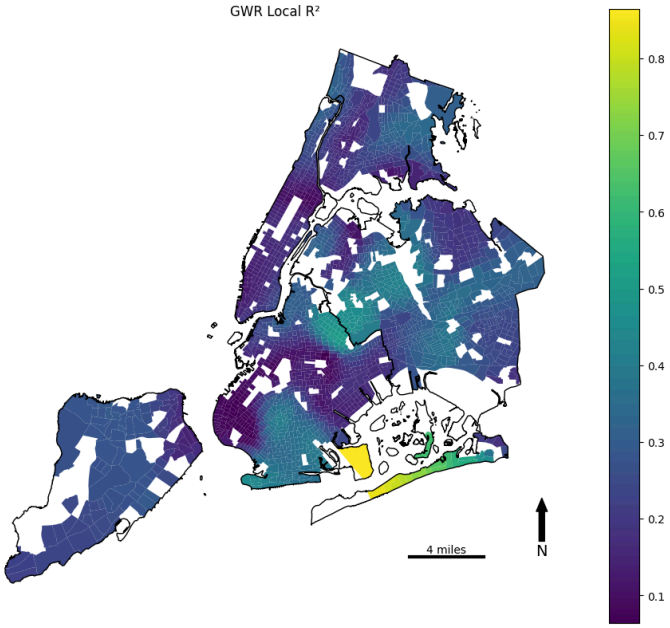

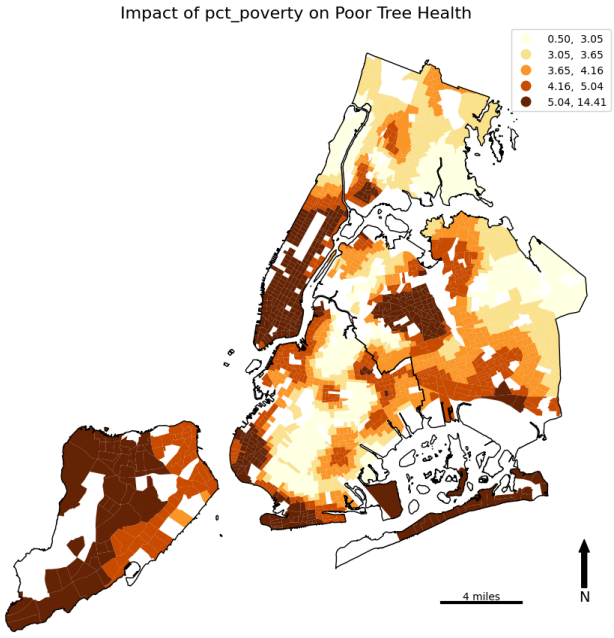

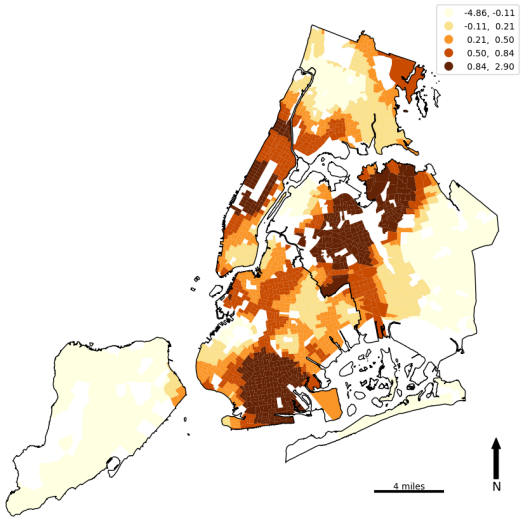

Mapping the Local R2's show that the current GWR model's power of explaining the variance in poor tree health is quite varied across the city, and mostly is moderate at best. The outlier regions in south Brooklyn (which is a golf course and sports field), and in the central Rockaways are interesting, and I'll have to examine them closer to understand this. My guess is they have low population densities, leading to whatever demographic is captured in the percentages to have a very high value.

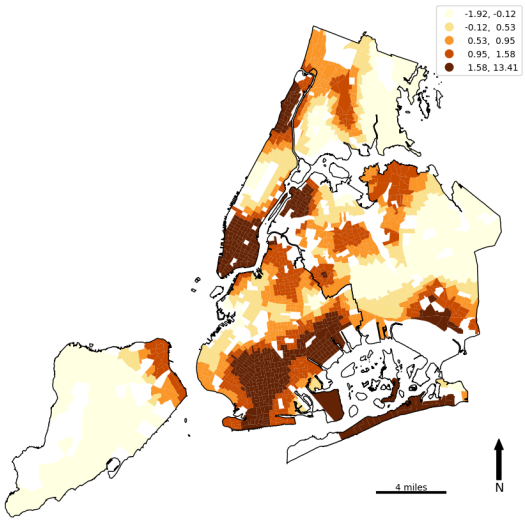

Once the GWR model is more robust, I aim to map out the coefficients of the predictors to see the spatial differences in the magnitude of their effect on poor tree canopy health. Currently the maps look like this and the following page, and they will be recreated after the GWR is polished.

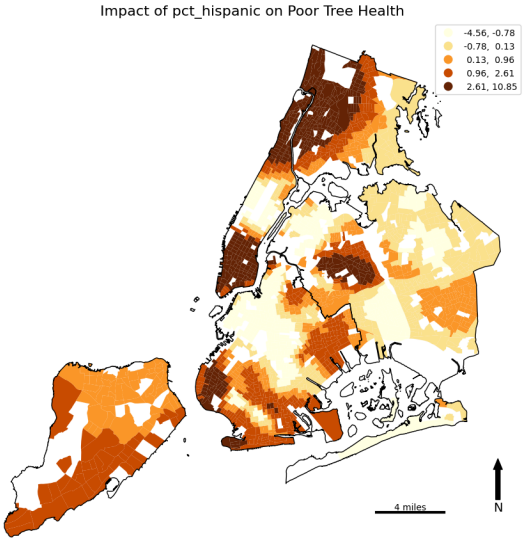

Impact of pct_bachelors_up on Poor Tree Health

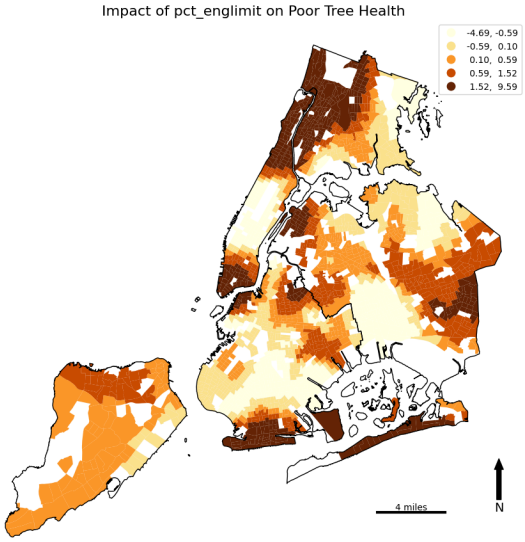

Impact of pct_black on Poor Tree Health

Impact of pct_hispanic on Poor Tree Health

Impact of pct_englimit on Poor Tree Health

Impact of imperv_resid on Poor Tree Health
